

Practical Meta-analysis in R

Saskia le Cessie Katerina Papadimitropoulou

5 April 2018

R and R-studio

- ▶ R is a programming language, originally 'written' in 1992 by Ross Ihaka and Robert Gentleman (yes, "R" stems from the first letter of their first names), inspired by another programming language called S.
- ▶ Throughout this practical you'll be encouraged to use R-studio. R-studio is a free, open-source "Integrated Development Environment" (IDE) for R (for Windows, Mac and Linux).
- ▶ Installing R-studio requires only two steps:
 - ▶ Download and install "base R" from the R project website:
<https://cloud.r-project.org/>.
 - ▶ Download and install R-studio from the R-studio website
<https://www.rstudio.com/products/rstudio/download/>.

Install and load libraries

```
# load libraries
install.packages(c("foreign", "metafor", "meta"))

library(foreign)
library(metafor)
library(meta)

# set your working directory
setwd("D:/Meta-analysis course LUMC")
```

EXERCISE I - Diuretic dataset

```
# Load the dataset  
diuretic = read.dta("diuretic.dta")  
  
# Take a look at the data  
View(diuretic)
```

- ▶ There are two ways to calculate the (log) odds ratios
 - ▶ Manually; first calculating the number of healthy subjects (without pre-eclampsia)
 - ▶ Using “escalc” function in R

EXERCISE I - Perform the MA

```
res1 = rma(yi, vi, data = diuretic, method = "FE",  
          measure = "OR")  
res1
```

```
##  
## Fixed-Effects Model (k = 9)  
##  
## Test for Heterogeneity:  
## Q(df = 8) = 27.2649, p-val = 0.0006  
##  
## Model Results:  
##  
## estimate      se      zval      pval      ci.lb      ci.ub  
## -0.3980  0.0893  -4.4548  <.0001  -0.5731  -0.2229  ***  
##  
## ---  
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

Forestplot - Fixed effects analysis

Random effects meta-analysis

```
res2 = rma(yi, vi, data = diuretic, method = "REML",  
           measure = "OR") # default
```

Many iterative and non-iterative approaches to estimate τ^2 :

$$Y_i = \theta + \theta_i + \epsilon_i$$

$$\theta_i \sim N(0, \tau^2)$$

$$\epsilon_i \sim N(0, V_i)$$

- ▶ DL: DerSimonian-Laird (most commonly used)
- ▶ EB: Empirical Bayes
- ▶ HE: Hedges
- ▶ Hs: Hunter-Schmidt
- ▶ ML: Maximum-likelihood
- ▶ REML: Restricted maximum-likelihood (default)
- ▶ SJ: Sidik-Jonkman

EXERCISE II - Streptokinase dataset

Odds ratio as outcome - using function "metabin" from package meta

Cumulative meta-analysis

```
res4 = metacum(res1, sortvar = year, pooled = "random")  
forest(res4)
```

EXERCISE III - cholesterol dataset

Fixed effects meta-analysis - Forestplot

Random effects meta-analysis

##

Random-Effects Model (k = 28; tau² estimator: REML)

##

tau² (estimated amount of total heterogeneity): 0.0313 (SE =

tau (square root of estimated tau² value): 0.1770

I² (total heterogeneity / total variability): 47.24%

H² (total variability / sampling variability): 1.90

##

Test for Heterogeneity:

Q(df = 27) = 49.6904, p-val = 0.0049

##

Model Results:

##

## estimate	se	zval	pval	ci.lb	ci.ub	
## -0.2128	0.0567	-3.7530	0.0002	-0.3240	-0.1017	***

##

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Forestplot with prediction interval

```
forest(res2, atransf = exp, slab = chol$trialname,
       addcred = TRUE, col = c("blue", "red"))
```

Meta-regression

Cholesterol level reduction as covariate

Meta-analytic Scatterplot

Observed outcomes (ORs) vs individual studies plotted against cholreduc

Funnelplot

Standard Error

Sampling Variance

Inverse Standard Error

Inverse Sampling Variance
